Stochastic dynamic programming with Markov chains for optimal sustainable control of the forest sector with continuous cover forestry

Peter Lohmander & Soleiman Mohammadi Limaei

Abstract

This paper presents a stochastic dynamic programming approach with Markov chains for optimal control of the forest sector. The forest is managed via continuous cover forestry and the complete system is sustainable. Forest industry production, logistic solutions and harvest levels are optimized based on the sequentially revealed states of the markets. Adaptive full system optimization is necessary for consistent results. The stochastic dynamic programming problem of the complete forest industry sector is solved. The raw material stock levels and the product prices are state variables. In each state and at each stage, a quadratic programming profit maximization problem is solved, as a sub problem within the STDP algorithm.

Keywords:

Optimization, Stochastic dynamic programming, Markov chains, Forest sector, Continuous cover forestry.

Introduction

How should these activities in a typical forest industry sector be optimized and coordinated in the presence of stochastic markets:

- ***Pulp and paper production and sales,***
 - ***Sawn wood production and sales,***
- ***Wood based energy production and sales,***
 - ***Raw material procurement and sales,***
 - ***Harvest operations, and,***
 - ***Logistic solutions?***

Structure of the method:

- For **each year** (or other period) and possible price and stock states, the **profit is maximized using quadratic programming**.
- The one year quadratic programming problems are considered as **subproblems within a stochastic dynamic programming Markov chain master problem**.
- The **master problem can be solved via linear programming**, and maximizes the expected present value of the forest sector over an infinite horizon.

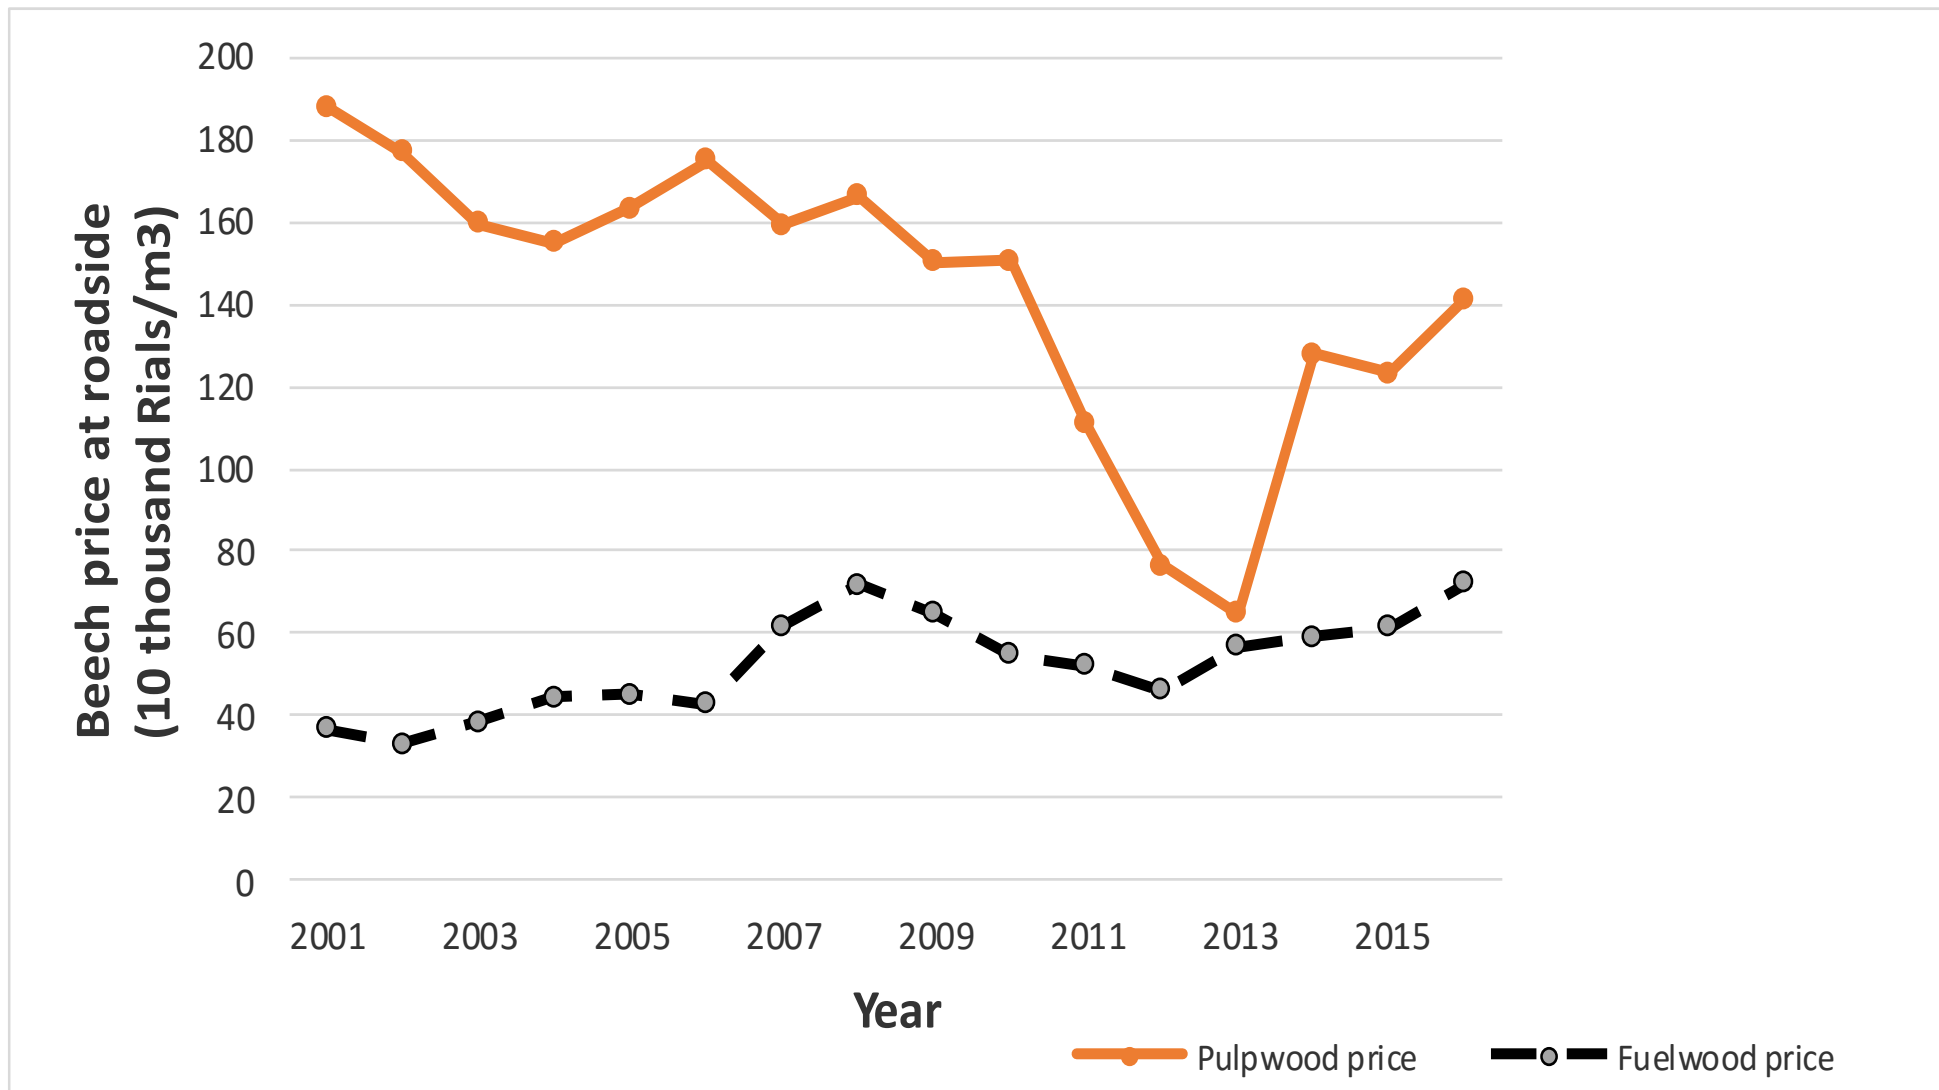

Figure 1. The inflation adjusted prices at roadside in Iranian Caspian forests for beech used for different purposes, namely pulpwood and fuelwood. The inflation adjustment has been made via CPI, the consumer price index. (The prices are shown in the price level of 2016.) Note that the relation between the pulpwood price and the firewood price has changed considerably over time. [1].

- The forest sector includes several types of industrial plants, such as pulp mills, sawmills and wood based energy plants.
- The statistics clearly shows that such plants have paid very different prices for the raw materials from the forests.
- One illustration of this is found in Figure 1. This variation in relative input prices is most likely based on **large variations in the relative prices in the pulp and energy markets.**
- In order to optimize the total profitability of the sector, **it is necessary to sequentially take price changes into account, and to adapt production in the optimal way.**

- **The prices are not only difficult or impossible to predict perfectly. The prices are also affected by the volumes produced and sold in the markets.**
- **These production volumes are decision variables in the present maximization problem.**
- **A particular year, we may approximate the prices as linear functions of the production volumes. With higher volumes, the prices fall.**
- **The cost function is assumed to be convex.**
- **The profit function becomes a strictly concave quadratic function of production volumes.**

- If we control the forest sector with several types of mills and products, we may also derive **prices of particular products as linear multidimensional functions of the production volumes of several products.**
- In typical cases, the product prices may be negatively affected by the production volumes of similar products.
- As a result, the approximation of the total profit function becomes a strictly concave quadratic multidimensional function of all production volumes.
- With linear constraints, representing wood resources, mill capacities and logistic constraints, we obtain a **quadratic programming maximization problem.**
- Such a problem can be solved with standardized software and converges to the **global maximum in a finite number of iterations.**

x_j is the production volume of product j and π is the profit.

p_j and r_{jk} are profit function parameters.

C_i is the capacity of resource i and

α_{ij} is the amount of that resource used per unit of product j .

$$\begin{aligned}
\max \quad \pi(x_1, \dots, x_K) = & p_0 + p_1 x_1 + \dots + p_K x_K + \\
& + r_{11} x_1^2 + r_{12} x_1 x_2 + \dots + r_{1(K-1)} x_1 x_{K-1} + r_{1K} x_1 x_K + \\
& + \dots \\
& + r_{K1} x_K x_1 + r_{K2} x_K x_2 + \dots + r_{K(K-1)} x_K x_{K-1} + r_{KK} x_K^2
\end{aligned}$$

$$s.t. \quad \begin{cases} \alpha_{11} x_1 + \dots + \alpha_{1K} x_K \leq C_1 \\ \dots \\ \alpha_{L1} x_1 + \dots + \alpha_{LK} x_K \leq C_L \end{cases}$$

- The quadratic profit maximization problems should be solved each time new information concerning stochastic market changes appear.
- It is quite possible to use hours, days, weeks or years as periods.
- Each period, the following problem should be solved:

$$\max \pi(x_1, \dots, x_K; u, t, s, m)$$

s.t.

$$\alpha_{11}(u, t, s, m)x_1 + \dots + \alpha_{1K}(u, t, s, m)x_K \leq C_1(u, t, s, m)$$

...

$$\alpha_{L1}(u, t, s, m)x_1 + \dots + \alpha_{LK}(u, t, s, m)x_K \leq C_L(u, t, s, m)$$

Note that the parameters of the maximization problem are functions of the changing values of

(u, t, s, m) .

These variables represent: control decisions exogenous to the quadratic profit maximization problem, time, the state of the forest resource and the state of the markets.

The many quadratic profit maximization problems, one for each period, state of the forest and state of the markets, may be embedded within a stochastic dynamic programming problem of the following type:

$$f(t, s_t, m_t) = \max_{u_t \in U(t, s_t, m_t)} \left(\left(\begin{array}{l} \max \pi(x_1, \dots, x_K; u_t, t, s_t, m_t) \\ \text{s.t.} \\ \alpha_{11}x_1 + \dots + \alpha_{1K}x_K \leq C_1 \\ \dots \\ \alpha_{L1}x_1 + \dots + \alpha_{LK}x_K \leq C_L \end{array} \right) + \beta \sum_{m_{t+1}} \tau(m_{t+1} | m_t) f(t+1, s_{t+1}(s_t, u_t), m_{t+1}) \right) \quad \forall (t, s_t, m_t) | (0 \leq t \leq T)$$

$$f(t, s_t, m_t) = \max_{u_t \in U(t, s_t, m_t)} \left(\left(\begin{array}{l} \max \pi(x_1, \dots, x_K; u_t, t, s_t, m_t) \\ \text{s.t.} \\ \alpha_{11}x_1 + \dots + \alpha_{1K}x_K \leq C_1 \\ \dots \\ \alpha_{L1}x_1 + \dots + \alpha_{LK}x_K \leq C_L \end{array} \right) + \beta \sum_{m_{t+1}} \tau(m_{t+1} | m_t) f(t+1, s_{t+1}(s_t, u_t), m_{t+1}) \right) \quad \forall (t, s_t, m_t) | (0 \leq t \leq T)$$

$f(t, s_t, m_t)$ is the expected present value of the forest sector as a function of time, state of the forest and state of the markets, given that all future decisions are optimally taken, conditional on future information.

$U(\cdot)$ is the set of feasible controls; controls that are exogenous to the period and state specific quadratic profit maximization problems.

$\tau(m_{t+1} | m_t)$ is the market state transition probability; the probability that the markets move from state m_t in period t to state m_{t+1} in the next period.

β denotes the one period discounting factor.

T is the time horizon.

Infinite time, Markov chains, stationarity and sustainability

- Sustainable systems are usually desired. We want the forests and the environment to last forever.
- Continuous cover forestry is easier to handle within the framework of dynamic programming than forestry with final harvests. Marginal harvest level changes more or less instantly affect the forest production level until the next period.
- With final harvests, the production is discontinuous and includes delays of many years between control and effects on the future wood flow.

Below, we make marginal changes of the problem, in order to make the exposition easier to follow.

Now, i_t denotes “state”.

i_t contains all of the information of s_t and m_t in the earlier part of this paper.

$$f^*(t, i_t) = \max_{u_t} \left(\pi^*(u_t; t, i_t) + \beta \sum_{i_{t+1}} \tau(i_{t+1} | t, i_t, u_t) f^*(t+1, i_{t+1}) \right)$$
$$u_t \in U(t, i_t)$$

Now, we assume stationarity. Hence,

$$f(t, i) = f(i)$$

We can determine the optimal values of $f(i)$, denoted

$f^*(i) = f_i^*$, in the following way:

Note that:

$$f_i \geq \pi^*(u; i) + \beta \sum_j \tau(j|i, u) f_j \quad \forall i, u | u \in U(i)$$

and

$$f_i^* = \pi^*(u^*; i) + \beta \sum_j \tau(j|i, u^*) f_j^*$$

The optimal values of f_i are determined via this linear programming problem:

$$\min Z = \sum_i f_i$$

s.t.

$$f_i - \beta \sum_j \tau(j|i, u) f_j \geq \pi^*(u; i) \quad \forall i, u \Big|_{u \in U(i)}$$

The optimal decisions, u_i^* , are those values of u_i that make the constraints binding.

In other words;

The constraints with zero slack indicate the optimal decisions.

General properties of the solutions

- Of course, optimal numerical results are functions of the particular parameter values used.
- The estimation of these parameter values is an empirical problem that has no room in this short theoretical and general analysis.
- Related models have however been studied in the past.
- Some of the general conclusions derived from earlier numerically specified versions of similar models are these:

When the future prices of the final products are stochastic:

- “The **expected present value of the profit is higher** when the suggested method is used instead of deterministic linear programming.
- The **expected dual variables** (shadow prices) associated with the industrial capacity restrictions are **underestimated via deterministic multi period linear programming**.
- Industrial **flexibility is valuable and the optimal levels of maximum production capacities are higher** than in a deterministic world.”
- These results were reported by Lohmander [2].
- More problem specific results may be obtained in several cases. Such results are reported in Lohmander [3], [4], [5], [6], [7] Lohmander and Mohammadi [8] and Olsson and Lohmander [9].

Conclusions

- A **general framework** for forest sector optimization has been presented.
- Several **examples** of related studies and particular results have been reported.
- Considerable **economic gains** should be expected if the suggested method replaces traditional stiff long term planning methods.
- Furthermore, the forest is managed via continuous cover forestry, which leads to **environmental advantages** compared to forest management with clear fellings.
- The **complete system is adaptive and sustainable.**
